Photovoltaics (Electricity)
Efficiency: 10%

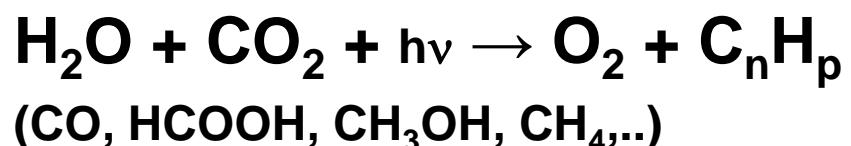

Artificial Photosynthesis

Electricity: DSSC

Rendt: 11%

- Reduction of CO_2

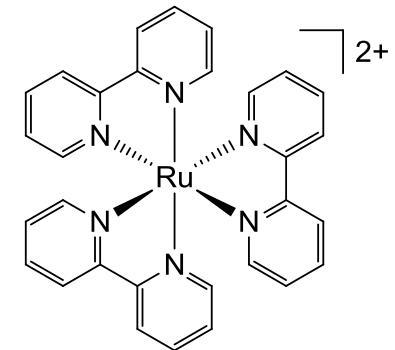

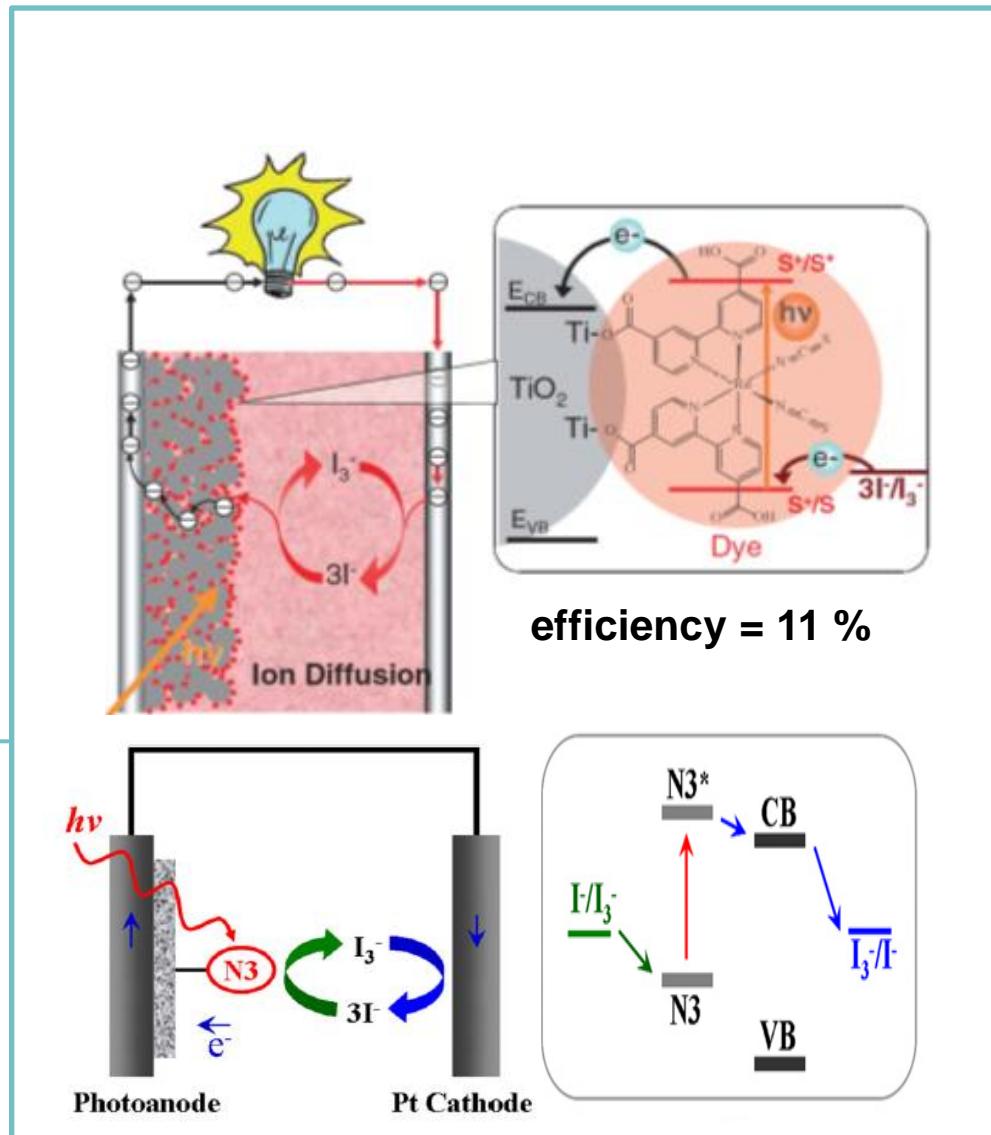

- Water splitting

Production of H₂: from sun and water ?

The « tough » part

- ΔG >> 0
- removal of 4 H⁺ and four e⁻ from water
- formation of an O-O bond
- light collection and conversion

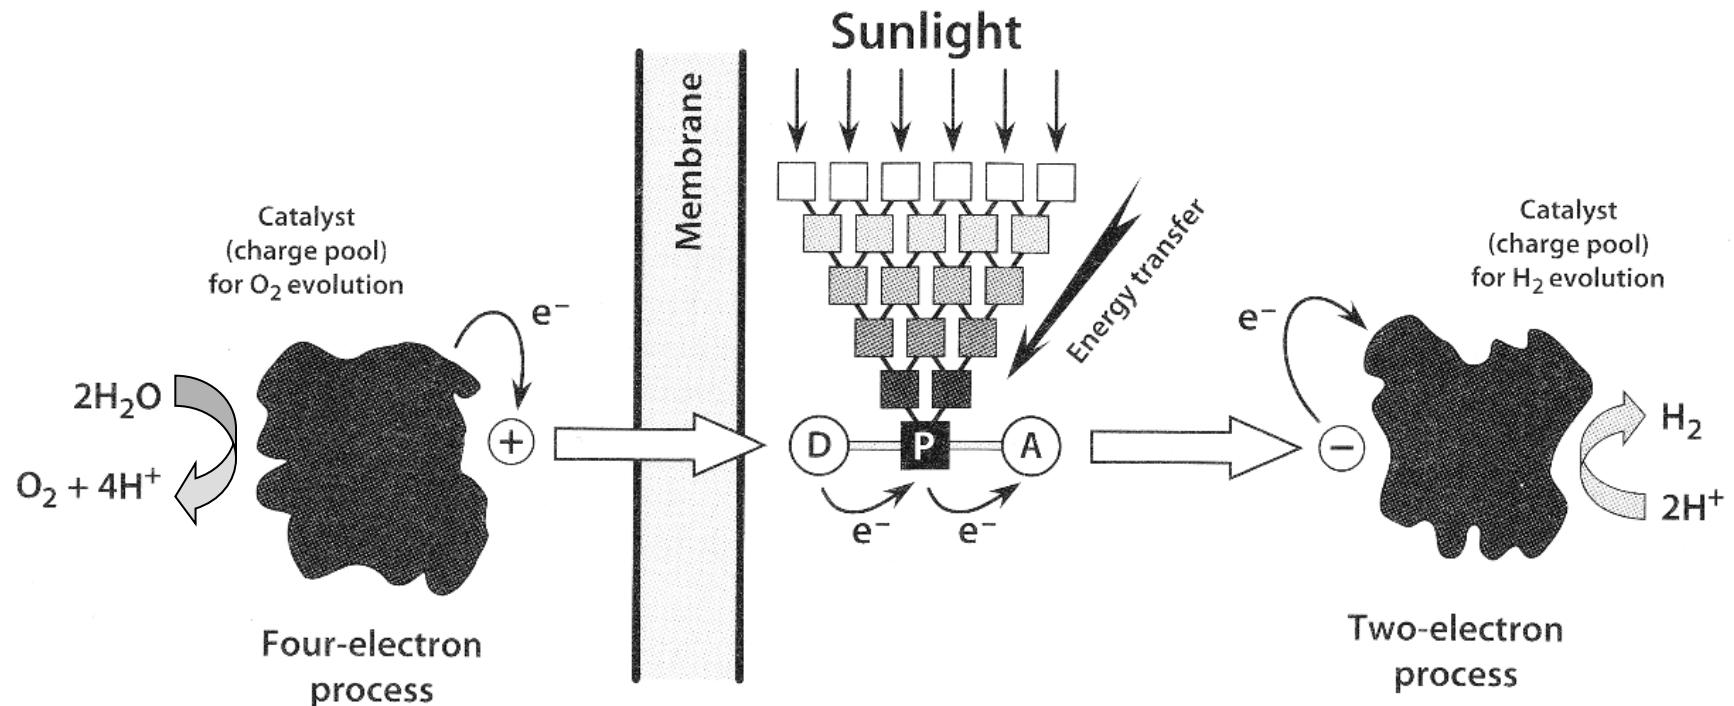

The « easy » part (somewhat tough)

- combining 2 H⁺ and 2 e⁻
- formation of an H-H bond

Artificial photosynthesis

Light harvesting: Separation of charges vs recombination

1. semiconductors: TiO_2 , WO_3 , Fe_2O_3 (hundreds tested)
2. Molecules: phtalocyanins, porphyrins, Ru, Ir, Re complexes

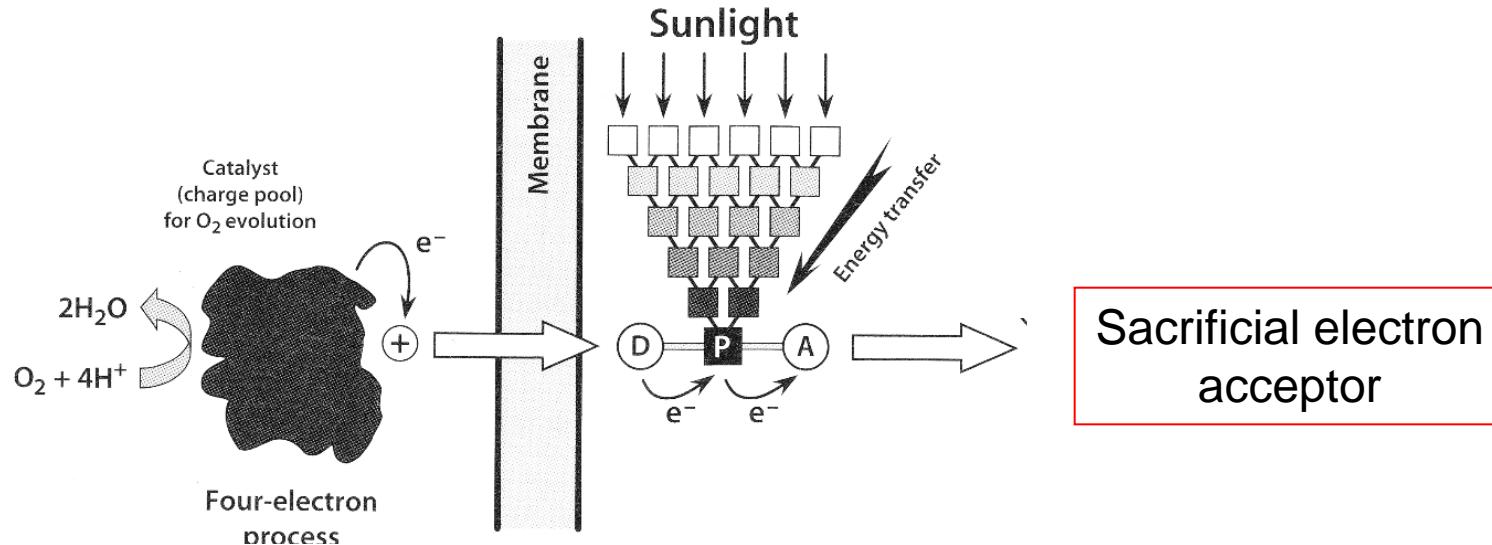

Catalysts:

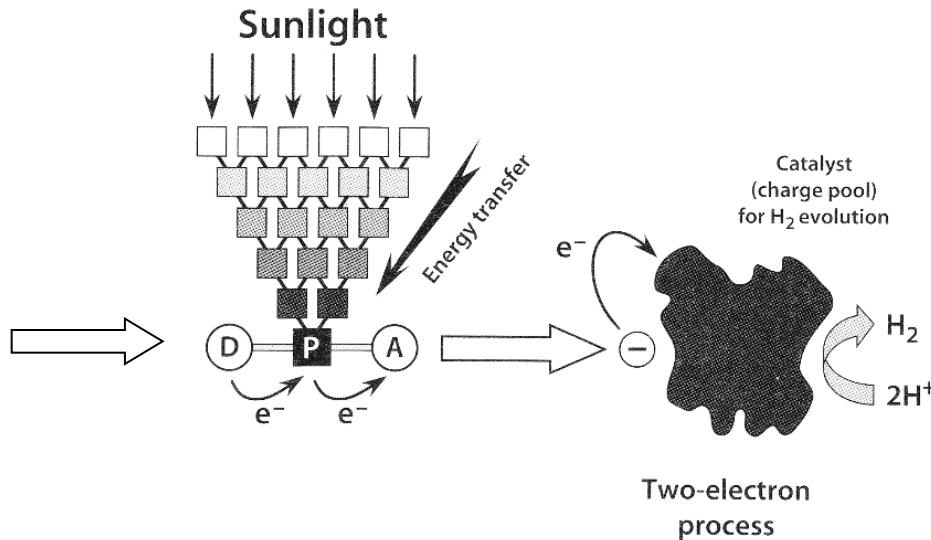

1. Accumulate several electrons (holes) one by one at constant potential close to the thermodynamic potential of the reaction
2. Deliver electrons (holes) to the substrate in a concerted manner

Mechanisms and optimization : sacrificial redox reagents

Large « driving force »
Charge recombination limited

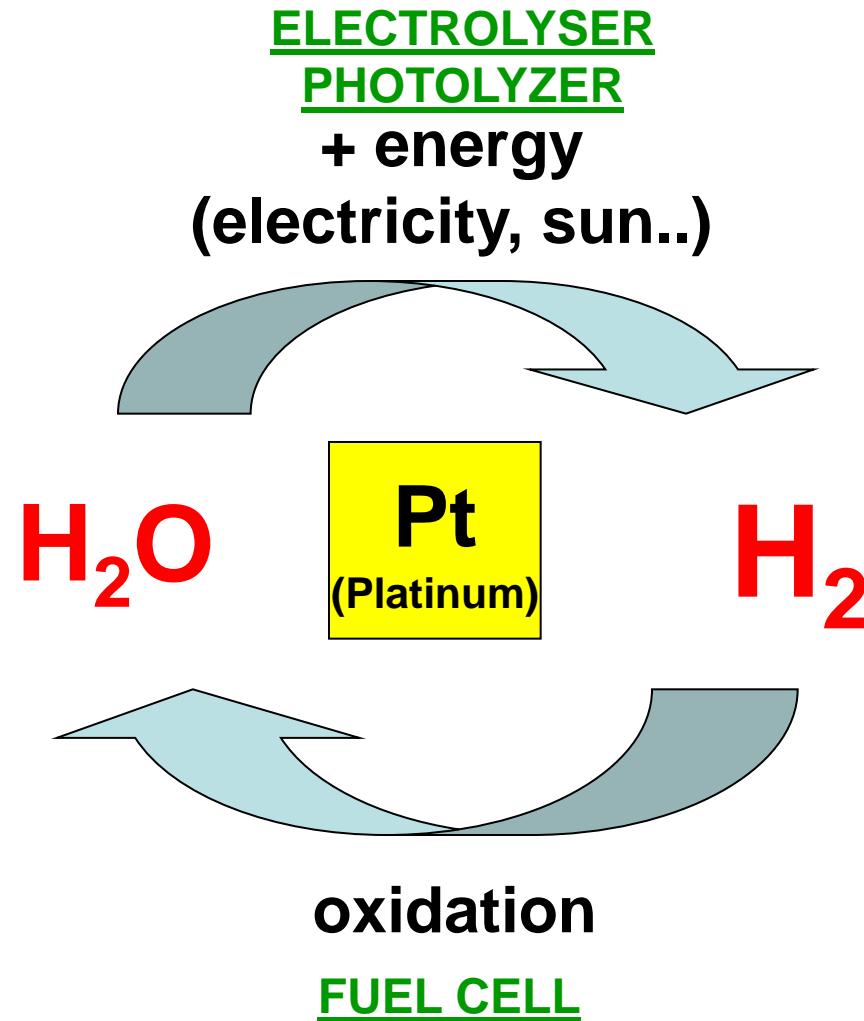

Sacrificial electron donor

The catalysis issue ?

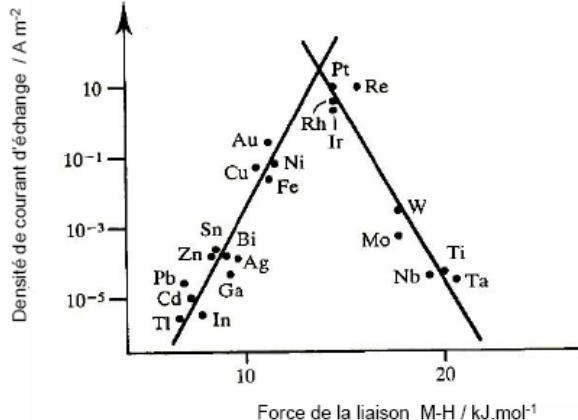

(for hydrogen production
and oxidation)

The catalysis issue

Water Photolysis: photoelectrochemical cells without noble metals

Photoanode: Fe_2O_3 ?

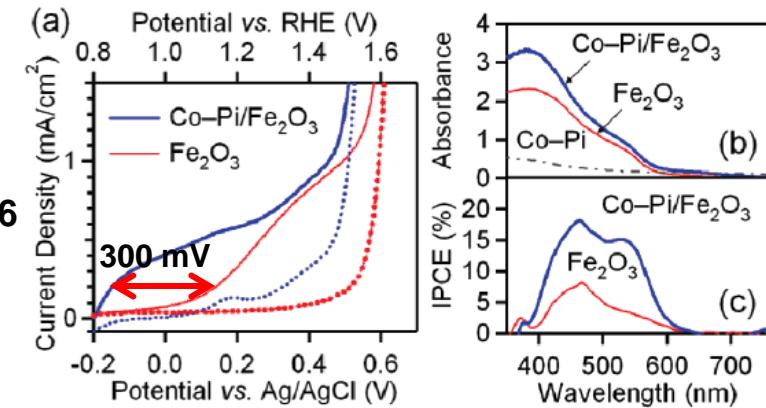

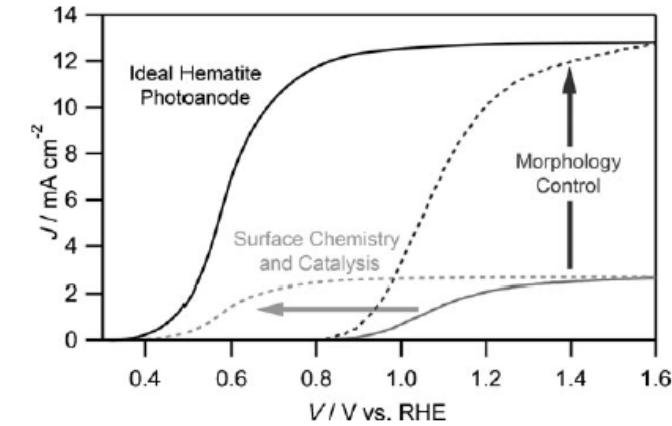

Advantages:

- Fe 2nd element on earth
- Visible light absorption ($2.1 \text{ eV} = 539 \text{ nm}$)
- Stability

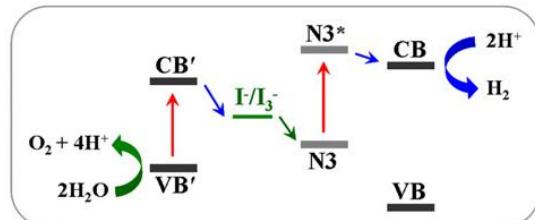

drawbacks:

- Too weak energy of the CB
- Low efficiency (<5-20%)
- ✗ low reactivity of surface « holes »
- ✗ slow diffusion of « holes » (few nm; $10^{-1} \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$)
- overvoltages
- catalysts

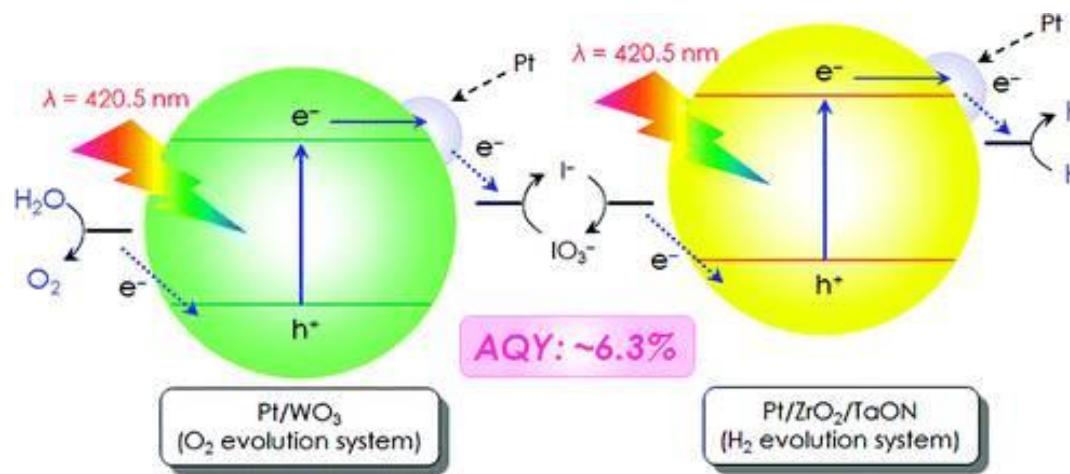

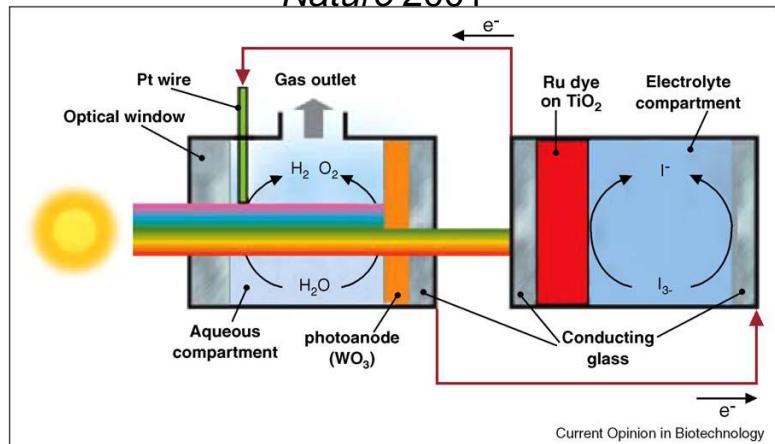

JACS 2009 131 6086

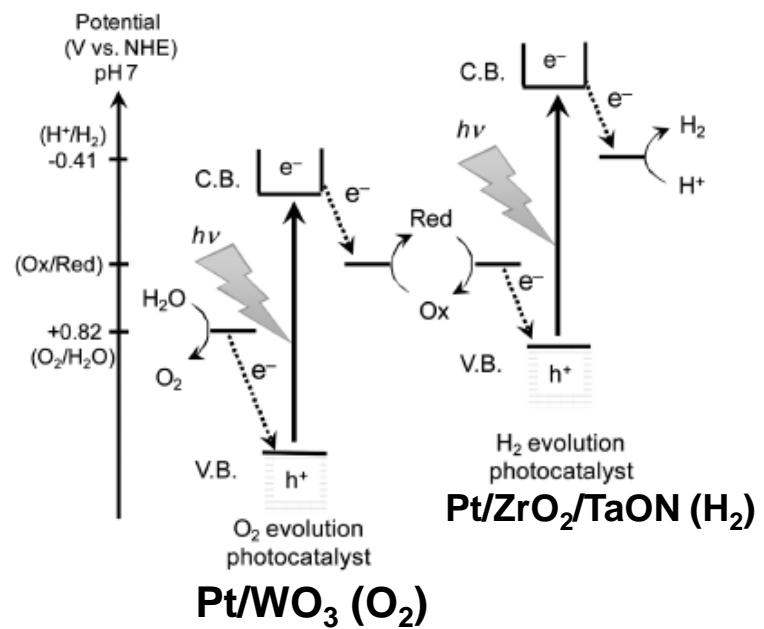

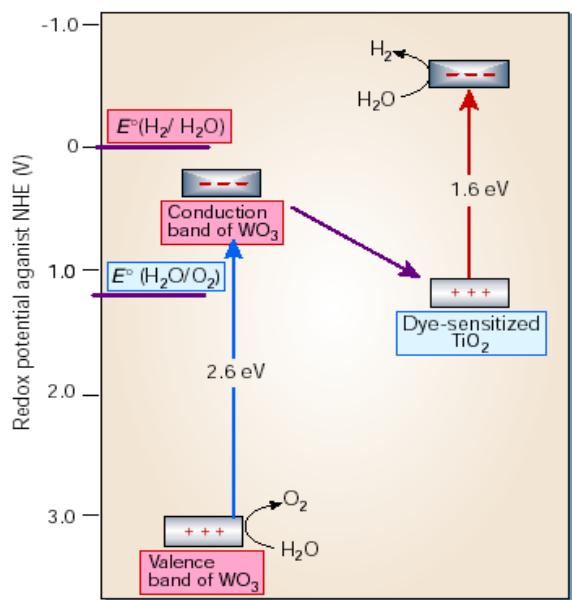

Photoanode: WO_3

European patent application EP-08 290 988.8

+++

A catalyst for oxidation and production of H₂
 >100.000 cat cycles !!

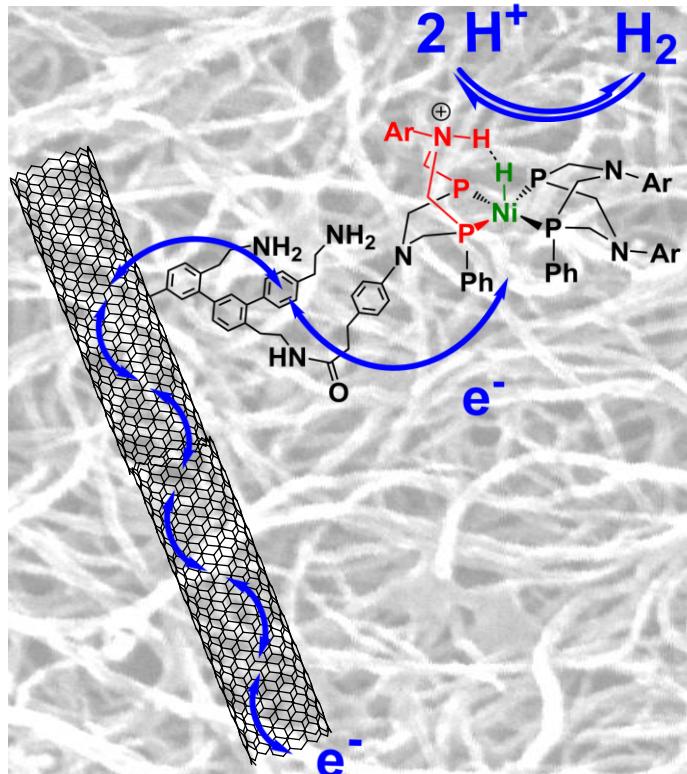

Stability

Compatible with PEM technology

Otvoltage= 20 mV !!

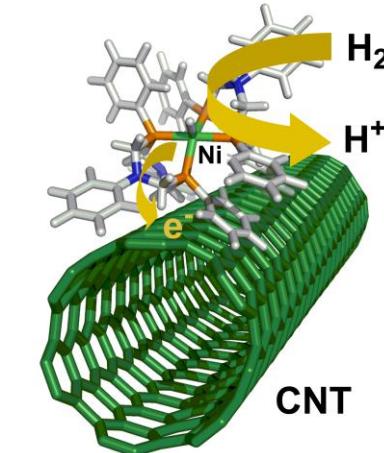

Resistance to CO

Cost: Ni 20 euros/kg (Pt: 20000 euros/kg)

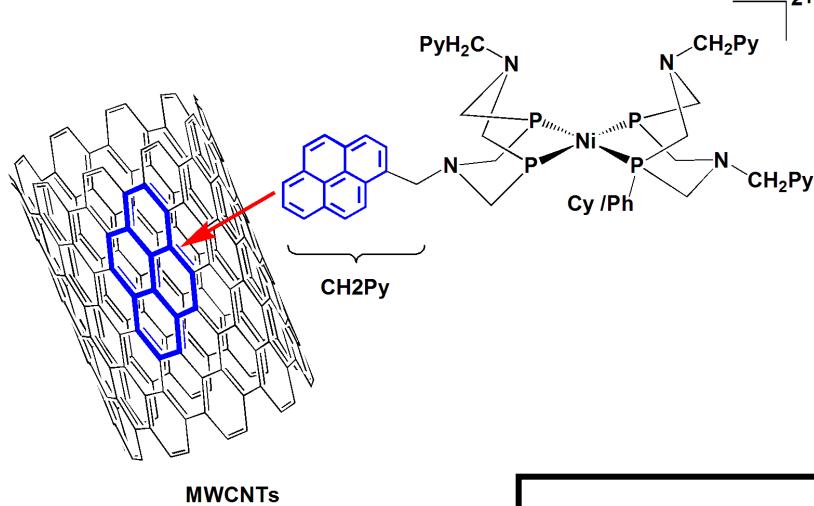

**A bioinspired Ni complex
grafted on NTCs
deposited on an electrode**

Weak current densities
 $\sim 4\text{--}5 \text{ mA.cm}^{-2}$
 (1/100 vs Pt)

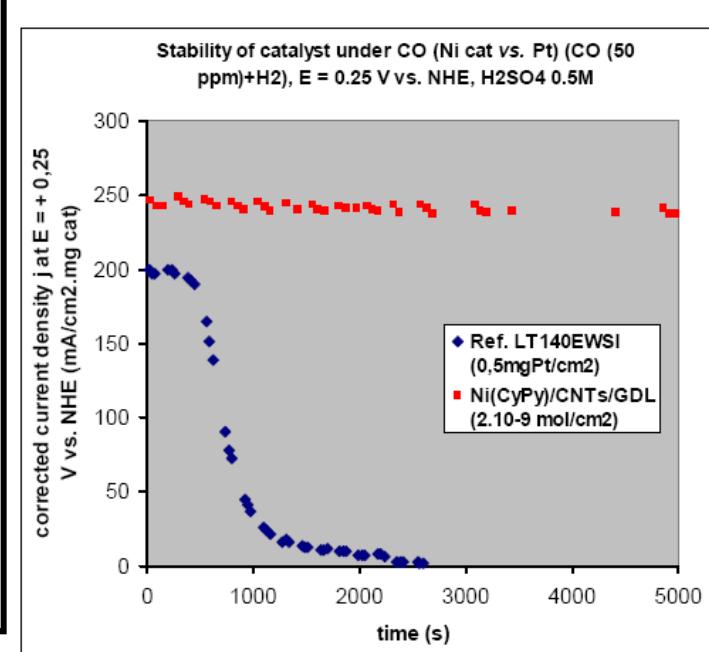

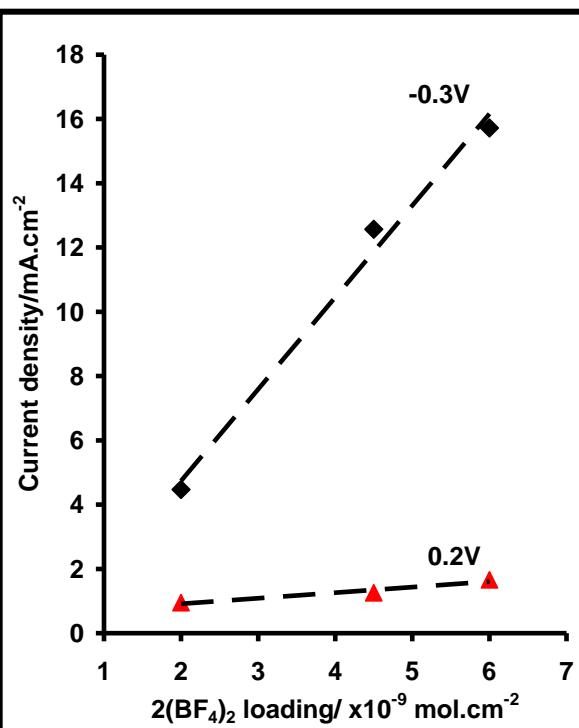

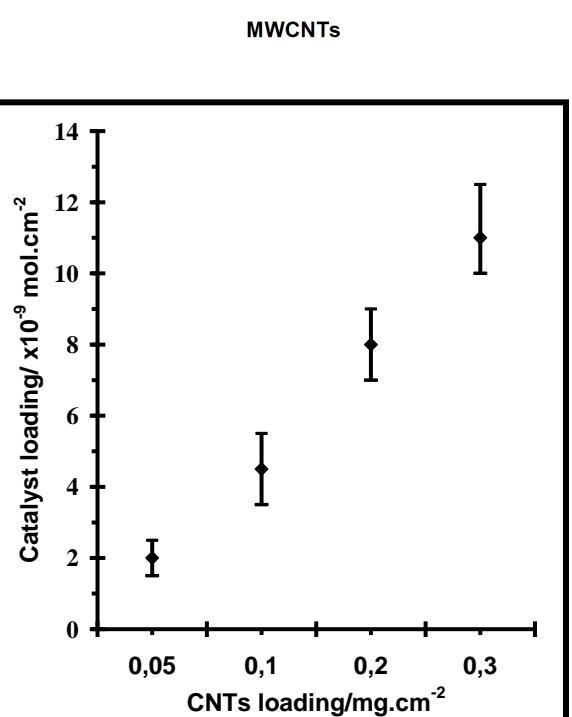

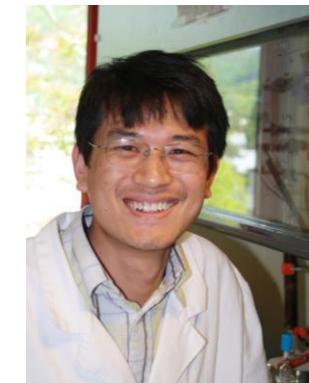

Optimization: new ligands/new immobilization methods

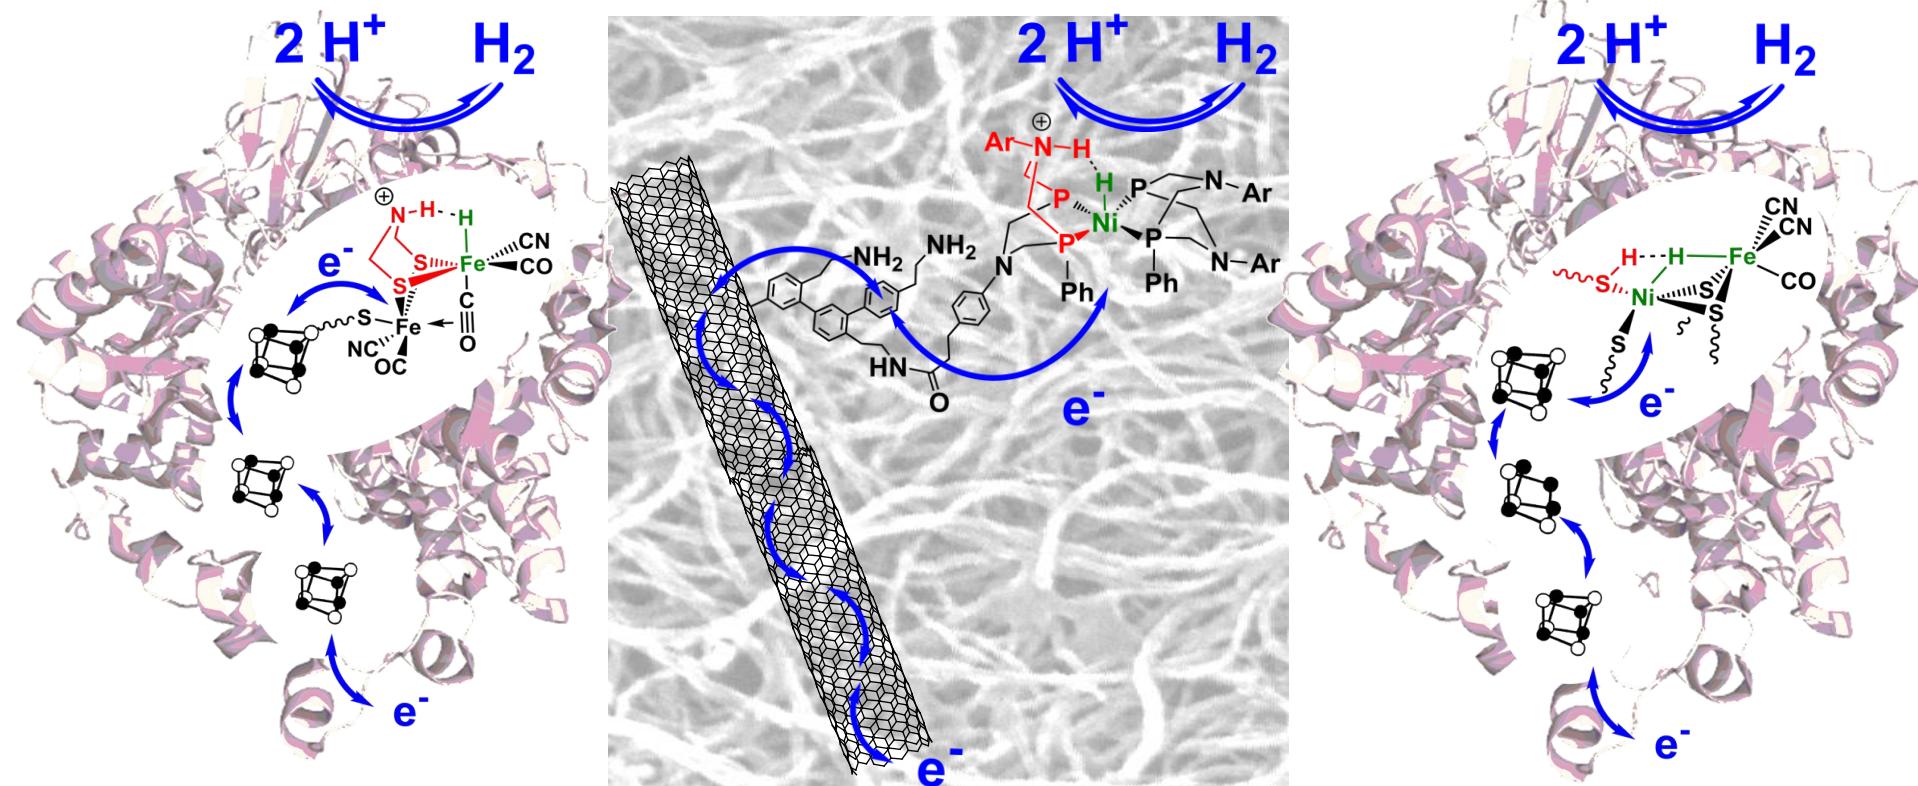

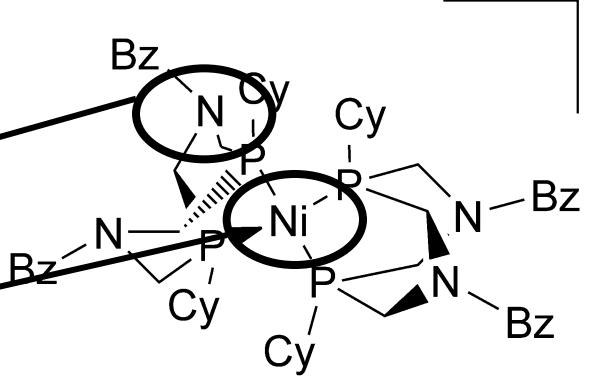

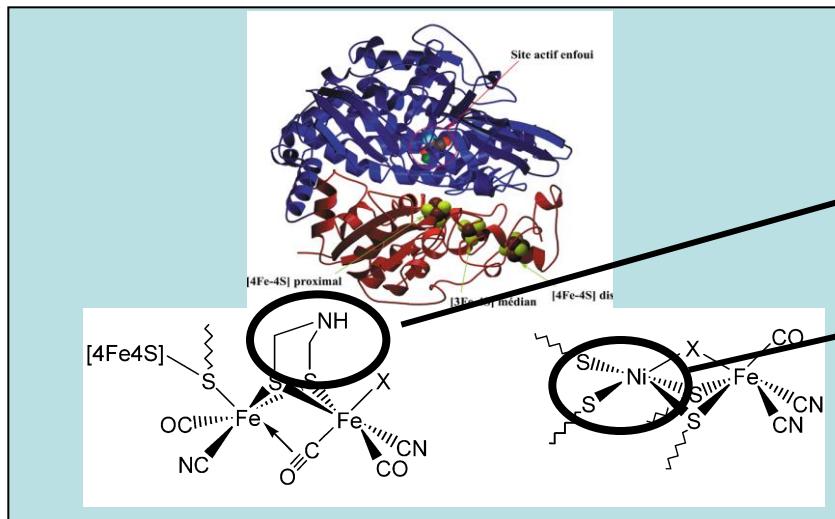

PD Tran, V Artero, M Fontecave et al.
Angew Chem 2011

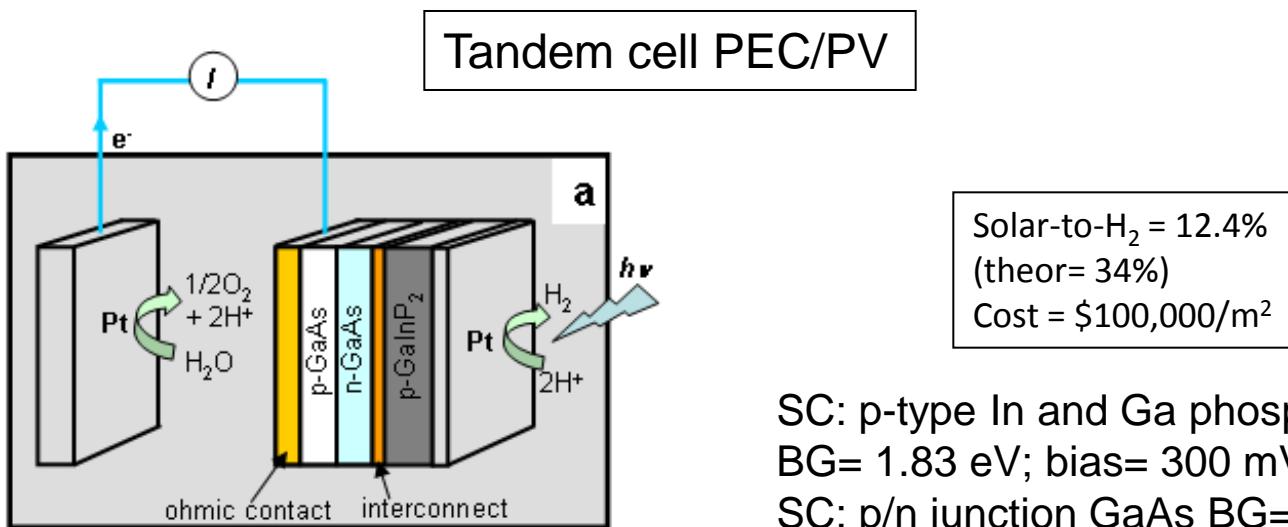

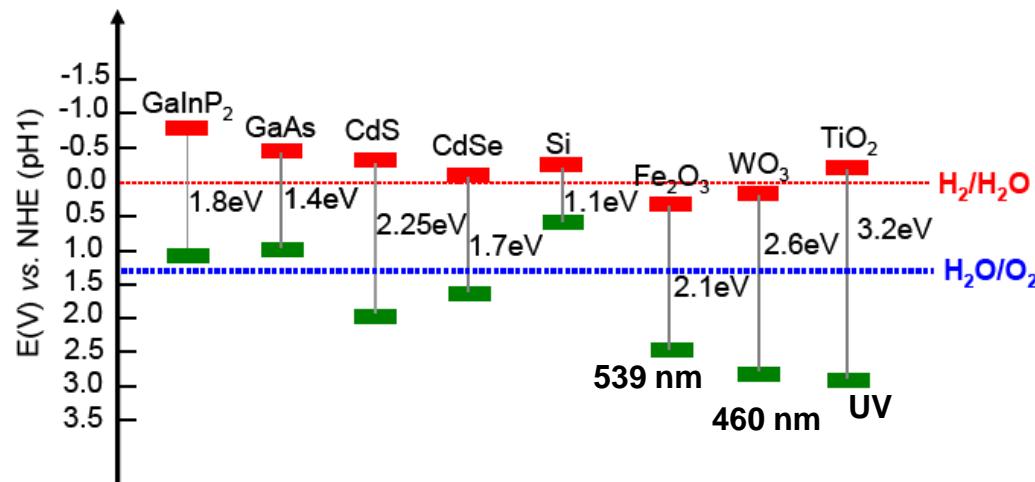

- Simplified preparation
- Catalyst loading ↑
- Current densities ↑

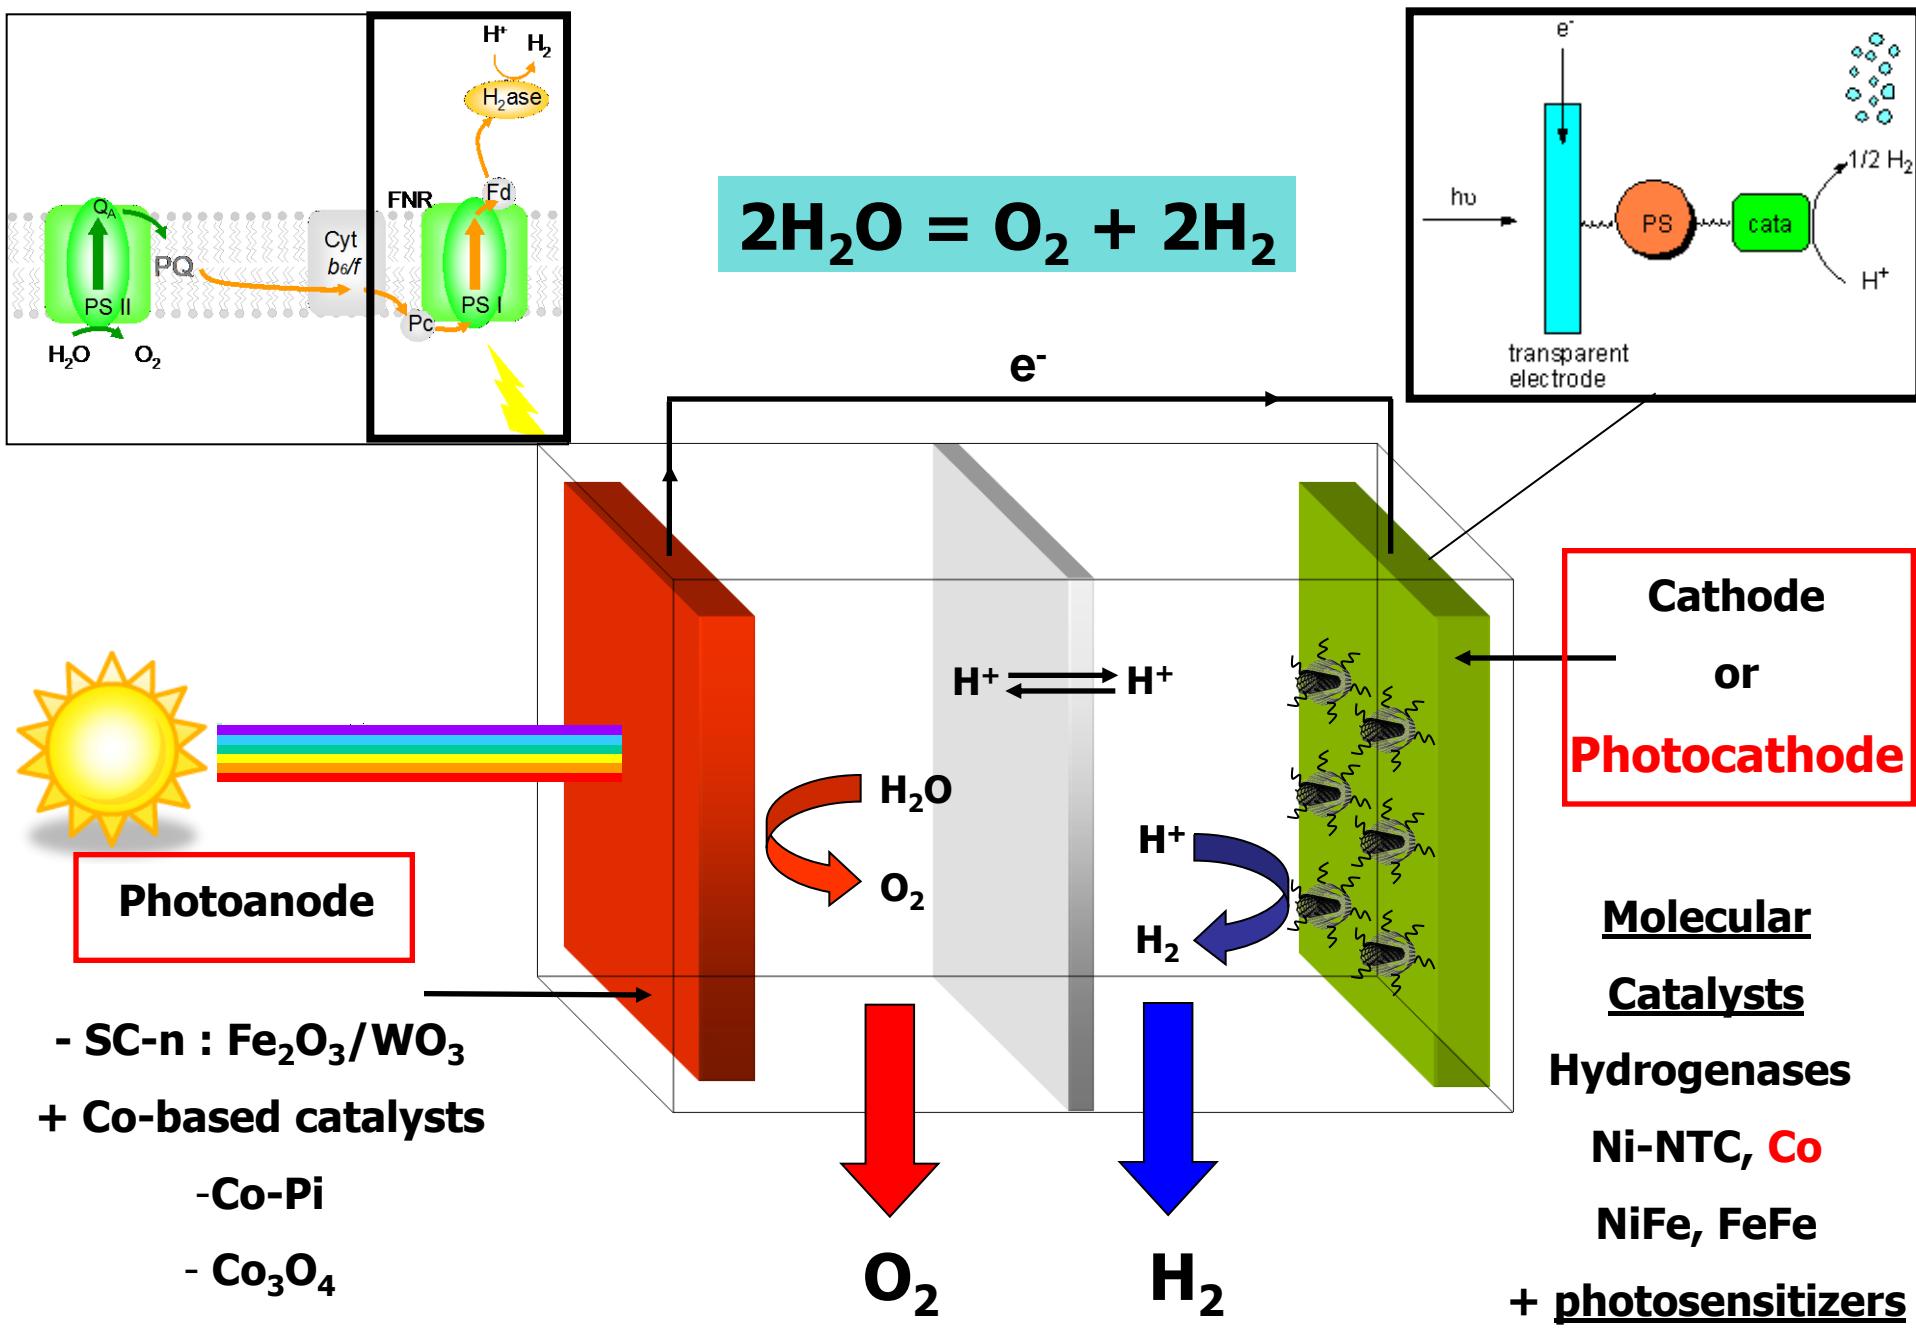

From enzymes to bio-inspired nanocatalysts

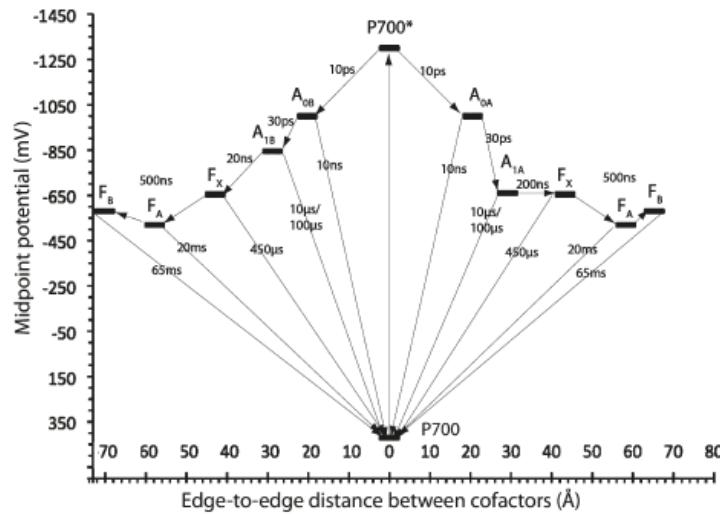

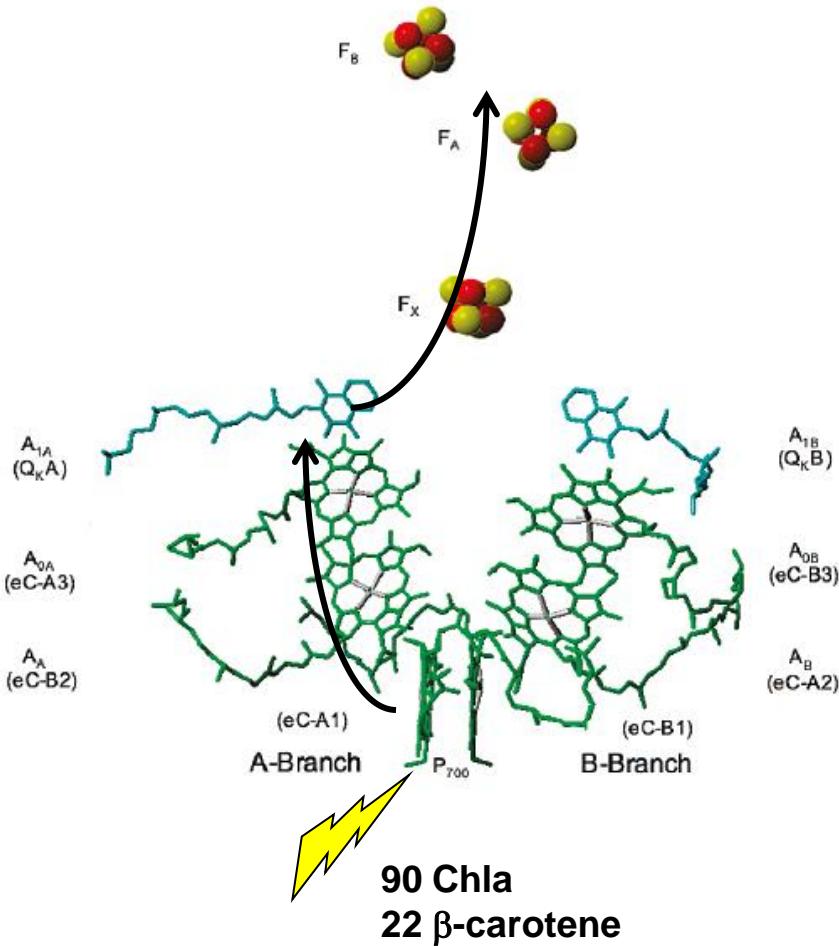

A photocathode ?

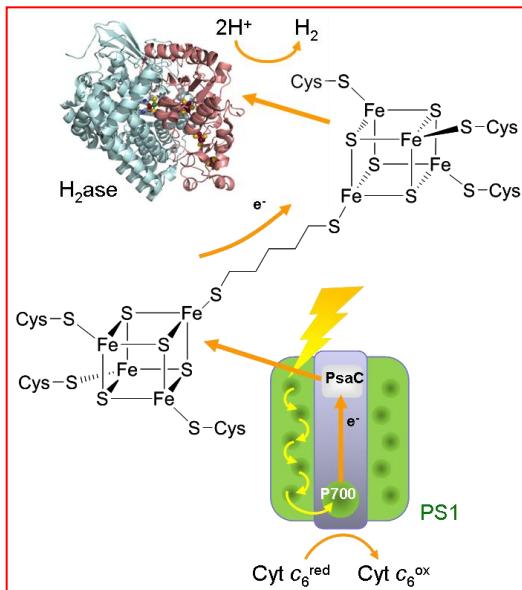

A « biological semiconductor »: PS1

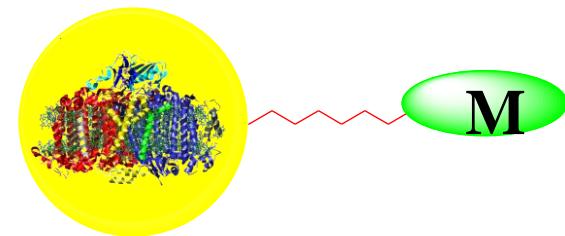

- ◆ PSI absorbs $\lambda < 700$ nm (45% solar spectrum; 1000 e⁻/s)
- ◆ Quantum yield= 1
- ◆ half life $P_{700}^+/F_B^- \tau = 60$ ms
- ◆ Potential $F_B^- E = - 580$ mV (< H⁺/H₂ by 166 mV)
- ◆ robust

« Biological » photocathodes: PS1 et hydrogenases

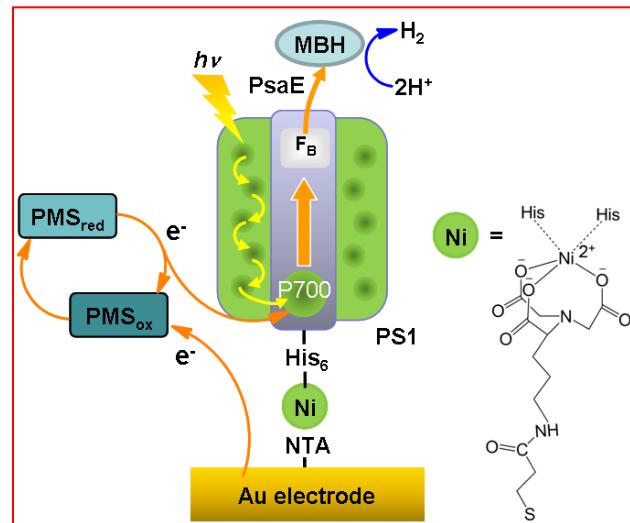

JH Golbeck JACS 2008 130 6308

PMS = methylphenazonium methyl sulfate

$4500 \pm 1125 \text{ mol H}_2 \text{ min}^{-1} \text{ mol}^{-1}$
PSI_{ΔPsaE}-MBH_{PsaE} hybride

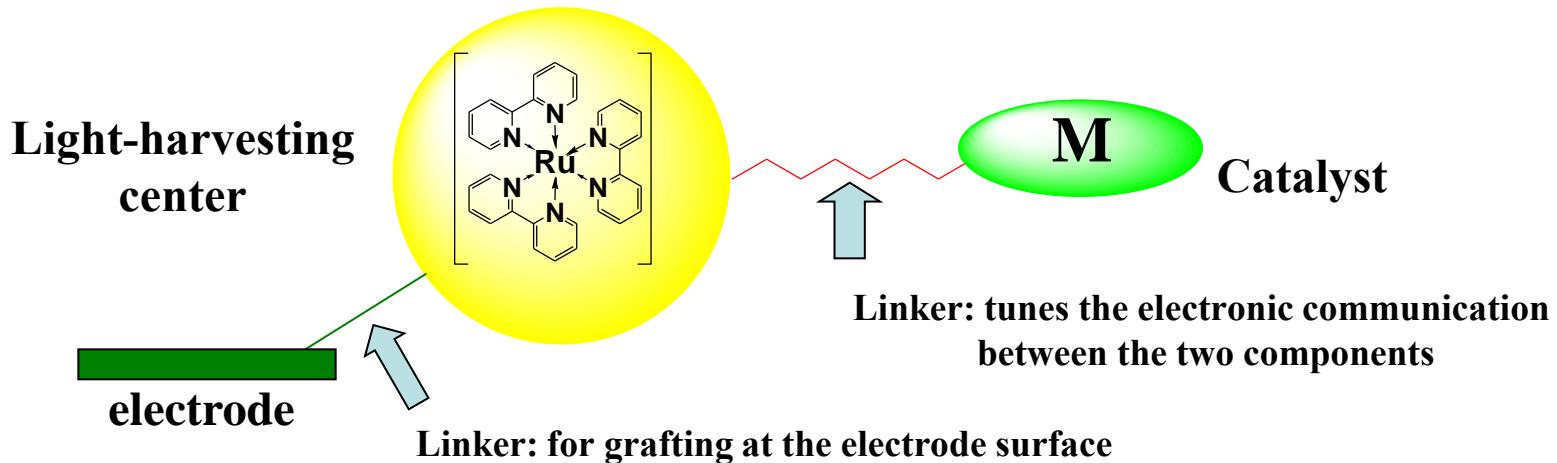

FA Armstrong, Chem. Commun. 2009, 550;
JACS 2009, 18467

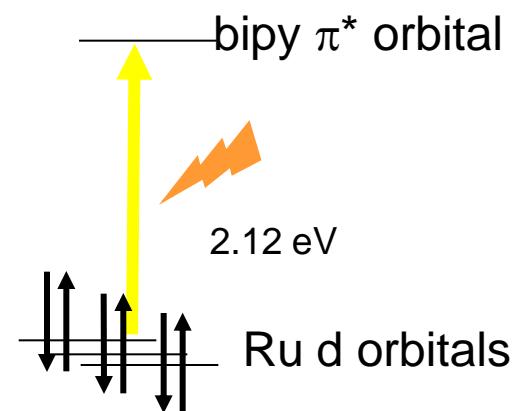

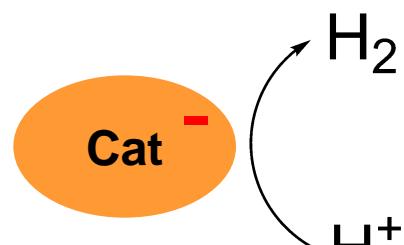

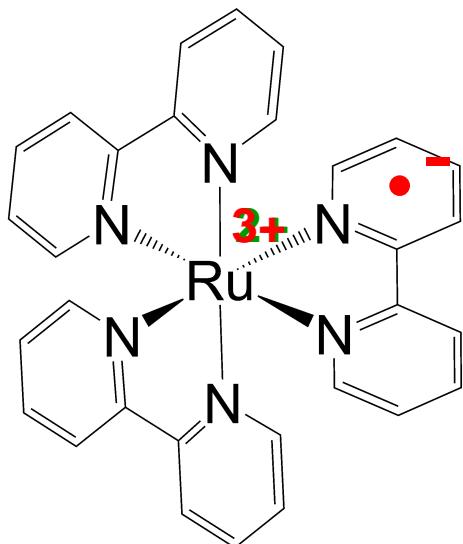

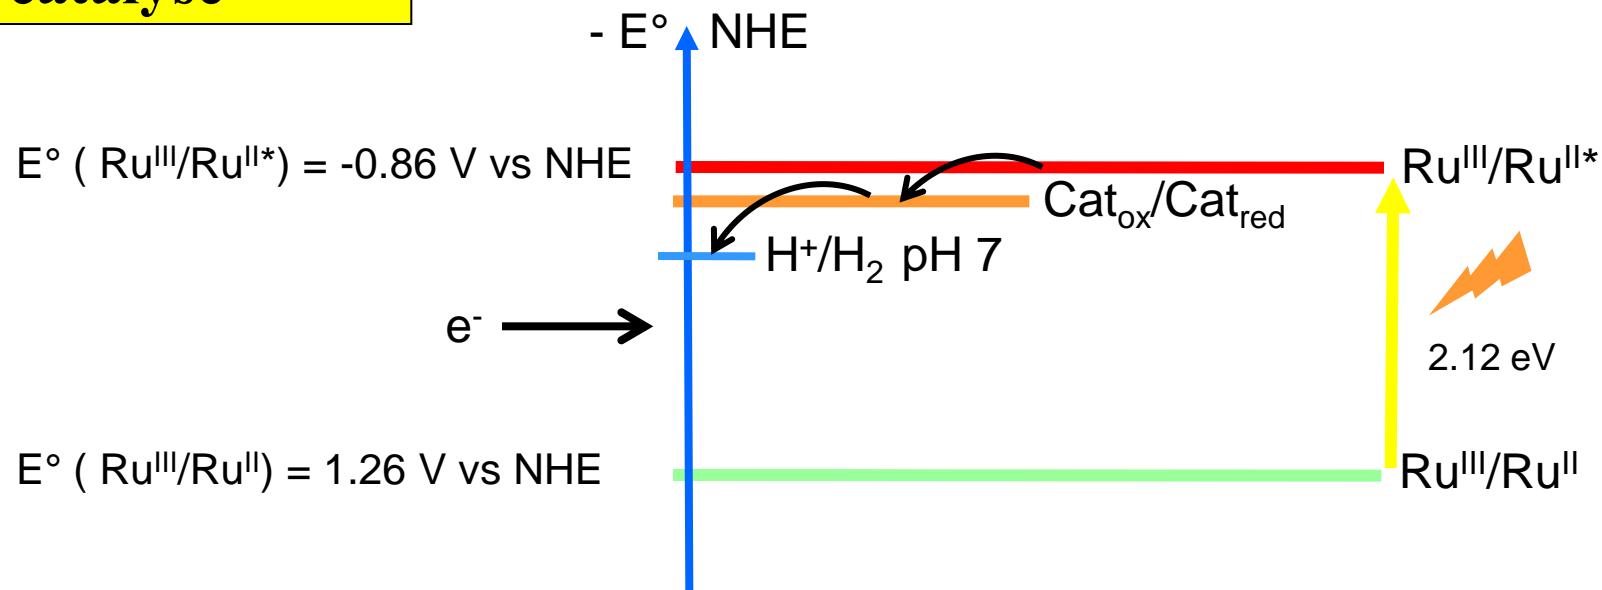

Towards a photocathodic molecular material

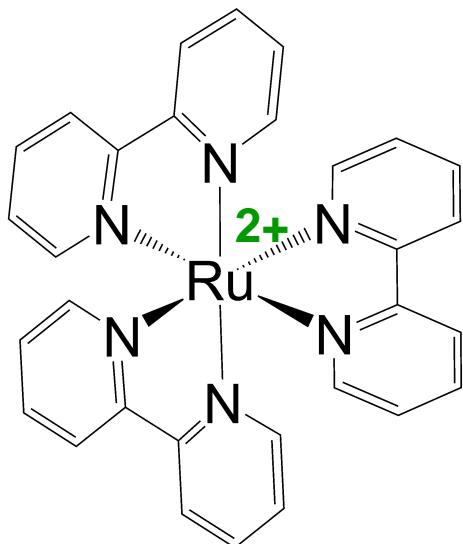

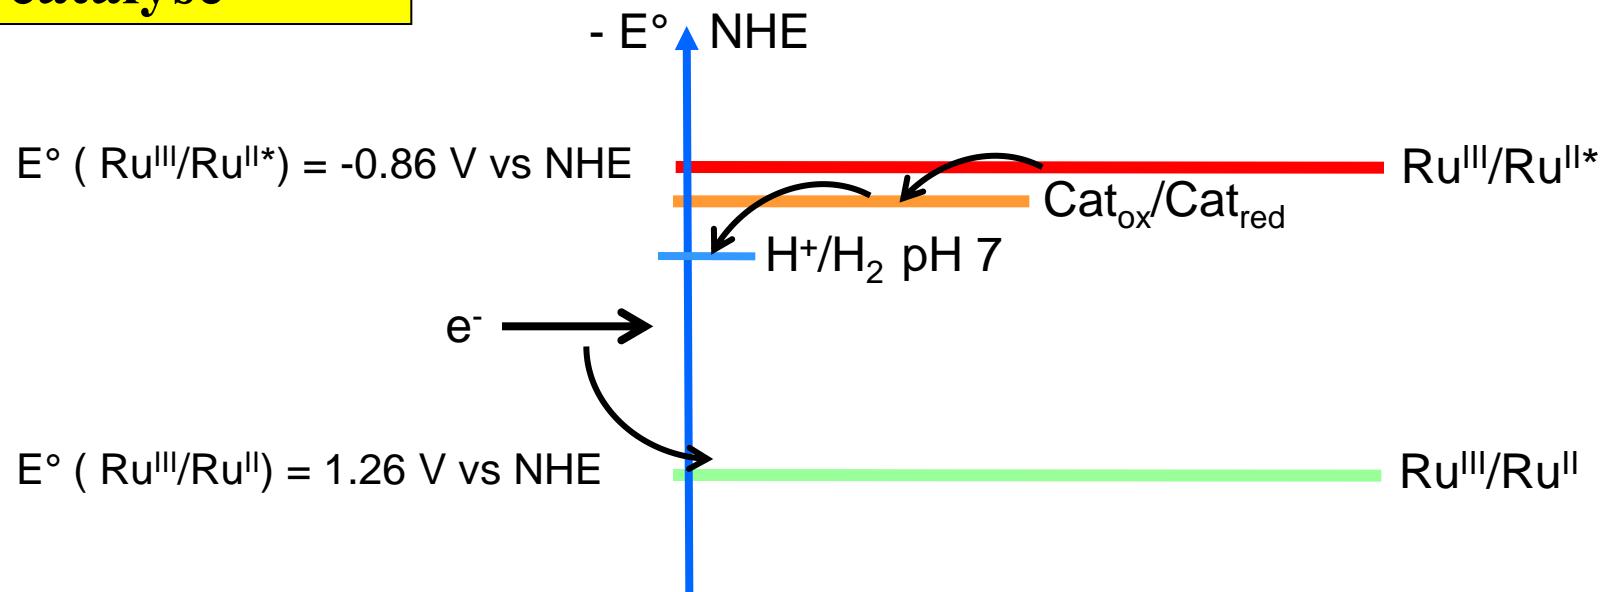

- ➡ Find the good **catalyst M** (cobaloximes,...)
- ➡ Find the good **photosensitizer** (high extinction coefficients, long-lived triplet excited state, photostability)
- ➡ Make a **multi-functional** (supramolecular) system
- ➡ Graft the compound on the **electrode surface**

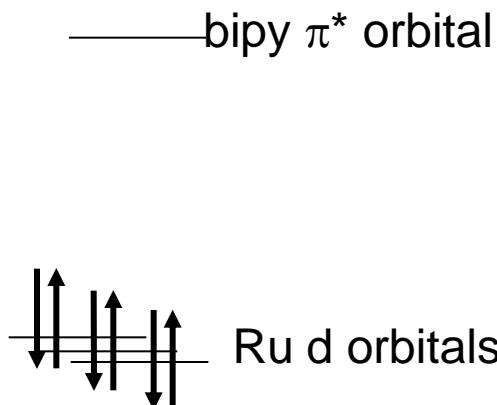

Photosensibilisation: catalyse

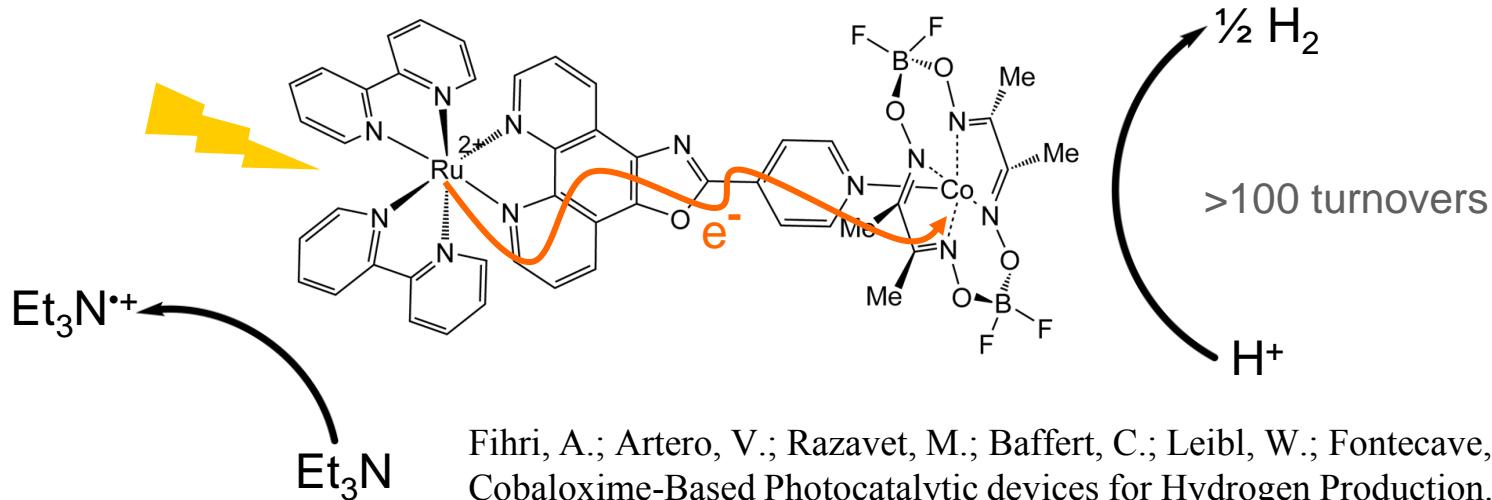

Photosensibilisation: catalyse

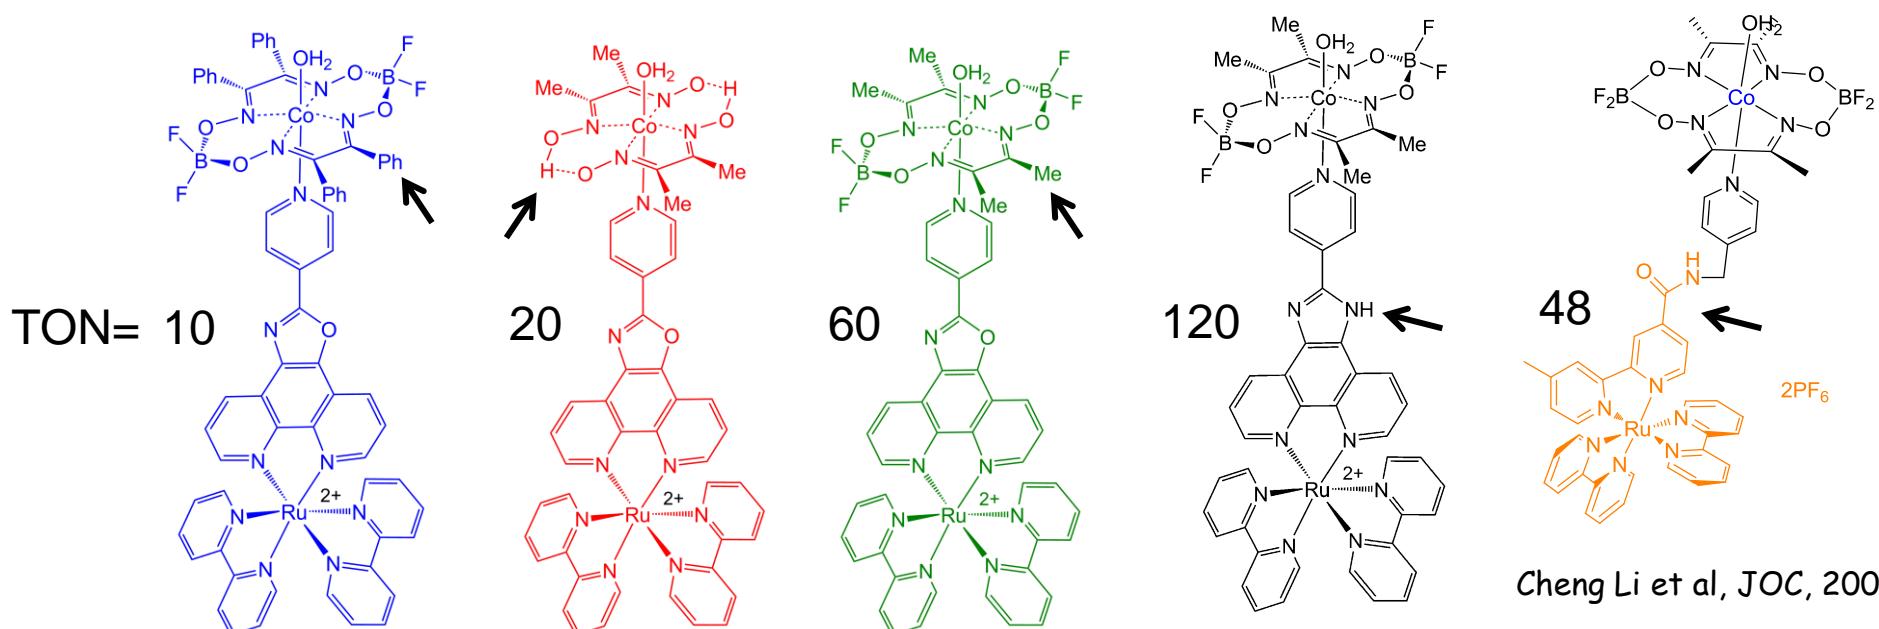

Cat

The first cobalt-based supra-molecular photocatalyst: cobaloximes

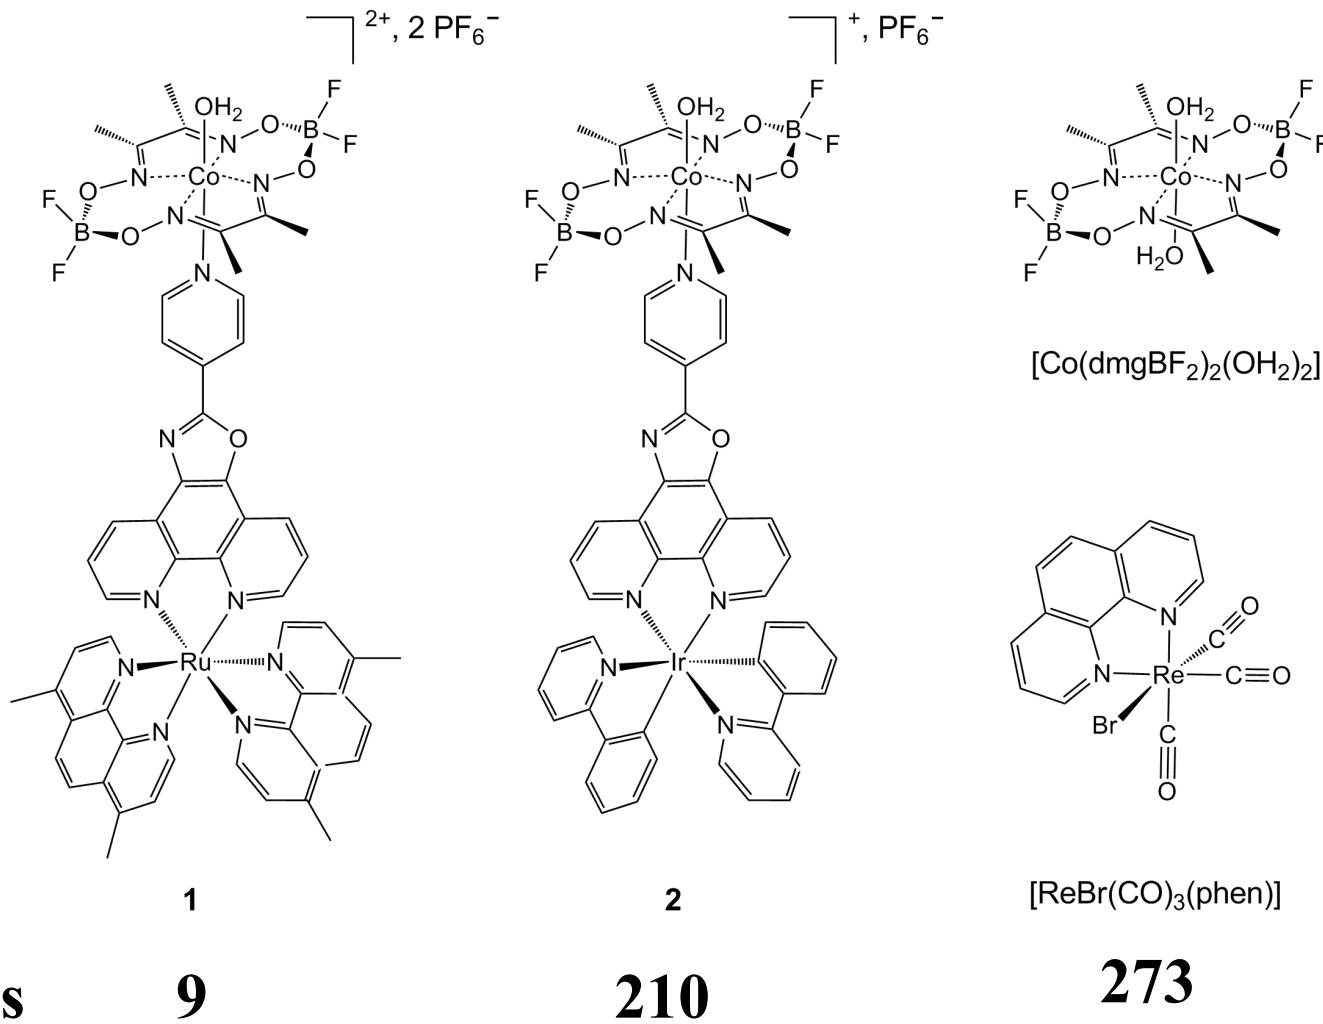

Fihri, A.; Artero, V.; Razavet, M.; Baffert, C.; Leibl, W.; Fontecave, M.,
Cobaloxime-Based Photocatalytic devices for Hydrogen Production.
Angewandte Chemie, International Edition **2008**

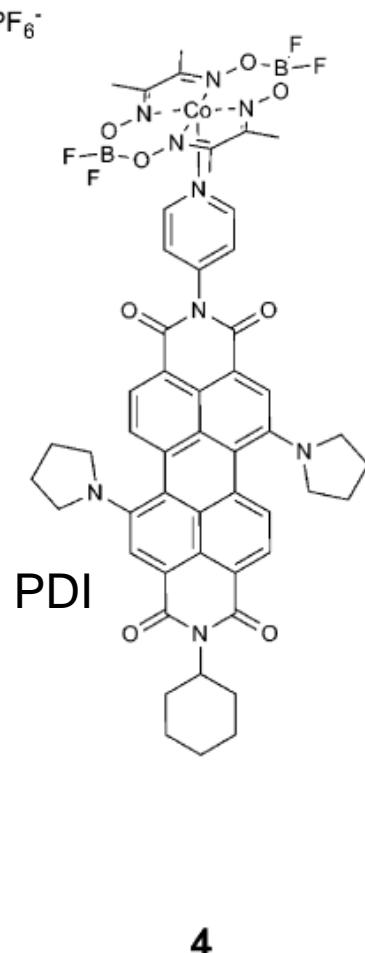

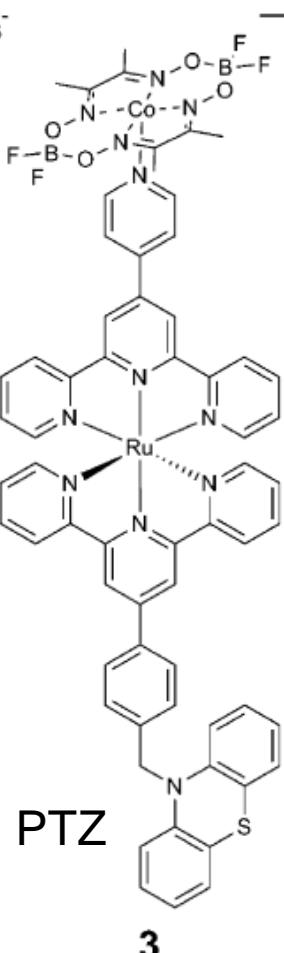

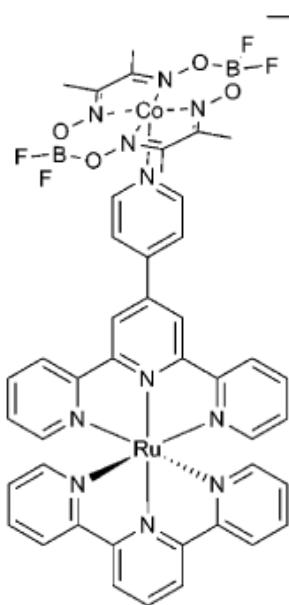

Cheng Li et al, JOC, 2009

A tunable supramolecular complex: the photosensitizer

Quantum yields: 16-18%

Further extensions

PDI= perylene-bis(dicarboximide)

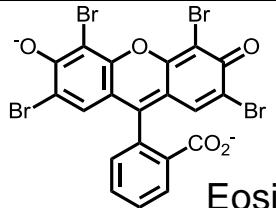

Conclusion 1:

3, with a phenothiazine (PTZ) secondary donor group, exhibits the largest excited state quenching (org solv)

Conclusion 2 (drawbacks):

- Significant disassociation of the cobaloxime and PS fragments
- Performances limited by cobaloxime decomposition
(R. Alberto, Inorg Chem 2010)

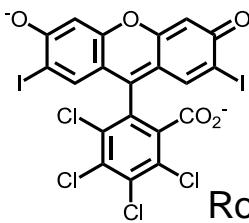

Further extensions: recent systems without noble metals

$\text{Co}(\text{dmgH})_2(\text{py})\text{Cl}$
+ excess dmgh

TON = 180 (12h)

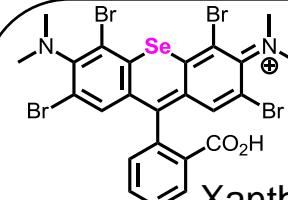

Eisenberg et al. *J. Am. Chem. Soc.* **2009**, 131, 9192.
